Motivation of Enumerability

Problem

Many functions are not computable or not efficiently computable.

Example

- #SAT:
How many satisfying assignments does a formula have?

Motivation of Enumerability

Problem

Many functions are not computable or not efficiently computable.

Example

For difficult languages A :

- Cardinality function $\#_A^n$:
How many input words are in A ?
- Characteristic function χ_A^n :
Which input words are in A ?

Motivation of Enumerability

Problem

Many functions are not computable or not efficiently computable.

Solutions

Difficult functions can be

- computed using probabilistic algorithms,
- computed efficiently on average,
- approximated, or
- **enumerated.**

How Well Can the Cardinality Function Be Enumerated?

What about 2-, 3-, 4-, ..., n -enumerability?

Cardinality Theorems Do Not Hold for All Models

Cardinality Theorems Do Not Hold for All Models

Why?

First Explanation

The weak cardinality theorems hold both for recursion and automata theory **by coincidence**.

Second Explanation

The weak cardinality theorems hold both for recursion and automata theory, **because they are instantiations of single, unifying theorems**.

Why?

First Explanation

The weak cardinality theorems hold both for recursion and automata theory **by coincidence**.

Second Explanation

The weak cardinality theorems hold both for recursion and automata theory, **because they are instantiations of single, unifying theorems**.

The second explanation is correct.

The theorems can (almost) be unified using first-order logic.

What Are Elementary Definitions?

Definition

A relation R is **elementarily definable in a logical structure \mathcal{S}** if

- there exists a first-order formula ϕ ,
- that is true exactly for the elements of R .

Example

The set of even numbers is elementarily definable in $(\mathbb{N}, +)$ via the formula $\phi(x) \equiv \exists z . z + z = x$.

Example

The set of powers of 2 is not elementarily definable in $(\mathbb{N}, +)$.

Characterisation of Classes by Elementary Definitions

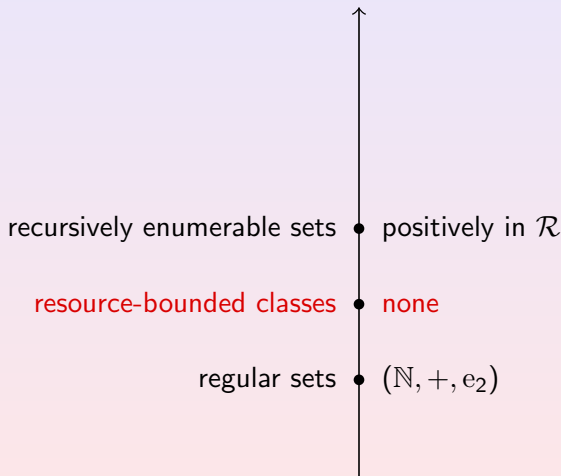

Theorem (Büchi, 1960)

There exists a logical structure $(\mathbb{N}, +, e_2)$ such that a set $A \subseteq \mathbb{N}$ is **regular** iff it is **elementarily definable in $(\mathbb{N}, +, e_2)$** .

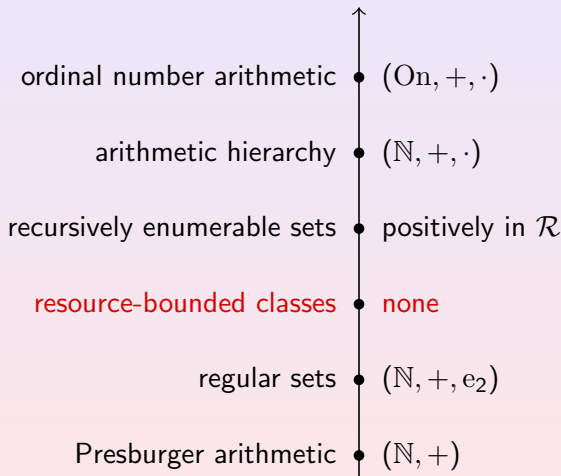

Theorem

There exists a logical structure \mathcal{R} such that a set $A \subseteq \mathbb{N}$ is **recursively enumerable** iff it is **positively elementarily definable in \mathcal{R}** .

Characterisation of Classes by Elementary Definitions

Characterisation of Classes by Elementary Definitions

Elementary Enumerability is a Generalisation of Elementary Definability

Definition

A function f is

elementarily m -enumerable in a structure \mathcal{S} if

1. its graph is contained in an **elementarily definable** relation R ,
2. which is **m -bounded**, i.e., for each x there are at most m different y with $(x, y) \in R$.

The Original Notions of Enumerability are Instantiations

Theorem

A function is m -enumerable by a **finite automaton** iff it is elementarily m -enumerable in $(\mathbb{N}, +, e_2)$.

Theorem

A function is m -enumerable by a **Turing machine** iff it is positively elementarily m -enumerable in \mathcal{R} .

The First Weak Cardinality Theorem

Theorem

Let \mathcal{S} be a logical structure with universe U and let $A \subseteq U$. If

- \mathcal{S} is well-orderable and
- χ_A^n is elementarily n -enumerable in \mathcal{S} ,

then A is elementarily definable in \mathcal{S} .

The First Weak Cardinality Theorem

Theorem

Let \mathcal{S} be a logical structure with universe U and let $A \subseteq U$. If

- \mathcal{S} is well-orderable and
- χ_A^n is elementarily n -enumerable in \mathcal{S} ,

then A is elementarily definable in \mathcal{S} .

Corollary

If χ_A^n is n -enumerable by a finite automaton, then A is regular.

The First Weak Cardinality Theorem

Theorem

Let \mathcal{S} be a logical structure with universe U and let $A \subseteq U$. If

- \mathcal{S} is well-orderable and
- χ_A^n is elementarily n -enumerable in \mathcal{S} ,

then A is elementarily definable in \mathcal{S} .

Corollary (with more effort)

If χ_A^n is n -enumerable by a Turing machine, then A is recursive.

The Second Weak Cardinality Theorem

Theorem

Let \mathcal{S} be a logical structure with universe U and let $A \subseteq U$. If

- \mathcal{S} is well-orderable,
- every finite relation on U is elementarily definable in \mathcal{S} , and
- $\#_A^2$ is elementarily 2-enumerable in \mathcal{S} ,

then A is elementarily definable in \mathcal{S} .

The Third Weak Cardinality Theorem

Theorem

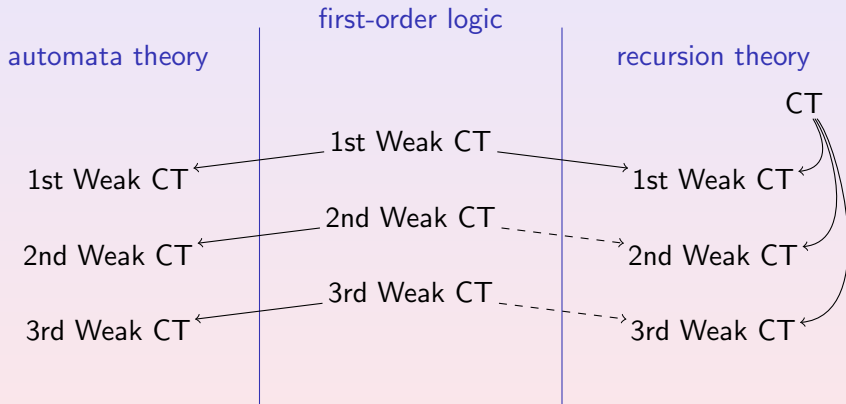

Let \mathcal{S} be a logical structure with universe U and let $A \subseteq U$. If

- \mathcal{S} is well-orderable,
- every finite relation on U is elementarily definable in \mathcal{S} , and
- $\#_A^n$ is elementarily n -enumerable in \mathcal{S} via a relation that **never** 'enumerates' both 0 and n ,

then A is **elementarily definable** in \mathcal{S} .

Theorem

Let \mathcal{S} be a well-orderable logical structure in which all finite relations are elementarily definable.

If there exist elementarily definable supersets of $A \times A$, $A \times \bar{A}$, and $\bar{A} \times \bar{A}$ whose intersection is empty, then A is elementarily definable in \mathcal{S} .

Note

The theorem is no longer true if we add $\bar{A} \times A$ to the list.

Summary

Summary

- The weak cardinality theorems for first-order logic **unify** the weak cardinality theorems of automata and recursion theory.
- The logical approach yields weak cardinality theorems for **other computational models**.
- Cardinality theorems are **separability theorems** in disguise.

Open Problems

- Does a cardinality theorem for first-order logic hold?
- What about non-well-orderable structures like $(\mathbb{R}, +, \cdot)$?
